

# Magnetoencephalography (MEG)

Frederick Carver PhD  
MEG Core Facility NIH

Our CTF system has 275 radial gradiometers, and 30 reference sensors (also EEG).

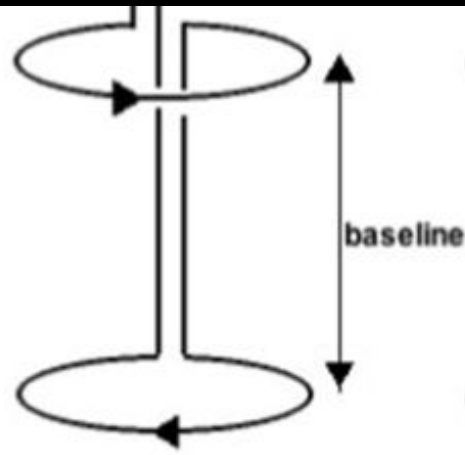

# SQuIDs

Superconducting Quantum Interference Devices

axial  
Magnetometer

1st-Order axial  
Gradiometer

1st-Order planar  
Gradiometer

# Signal Source

The long apical dendrites of cortical pyramidal cells are the theoretical source of MEG signals

Up to 10,000 parallel cells need to be active to produce measurable fields outside the head

A typical evoked field is on the order of 100 femto Tesla

(1fT =  $10^{-15}$ T)

# Comparison to EEG

Magnetic fields pass through the skull without interference

Volume conduction distorts EEG signals making source reconstruction difficult

Some sources may be harder to see with MEG because of orientation, or cancellation. e.g. SMA

# MEG Example

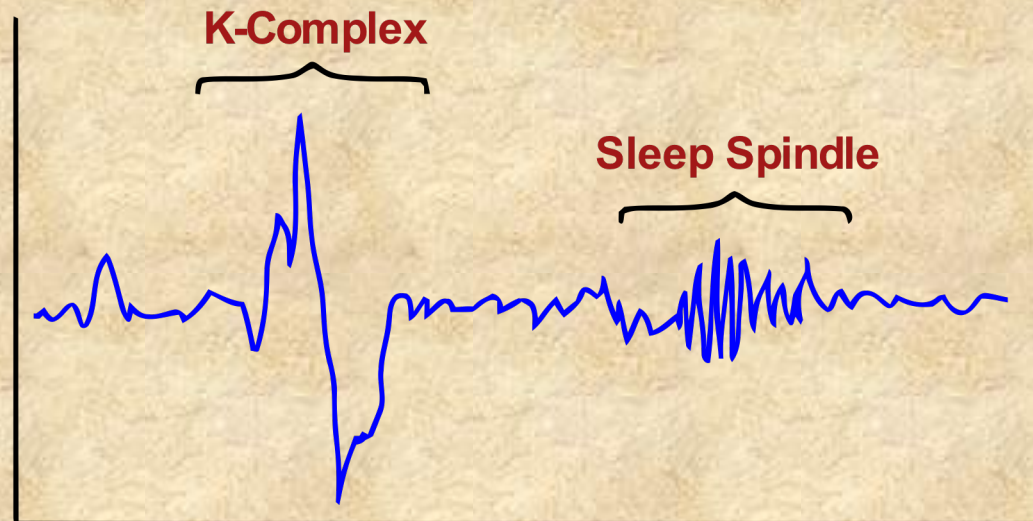

Epileptic spike associated with muscle twitch

Sato et al.,  
NINDS

# Time Series Analysis

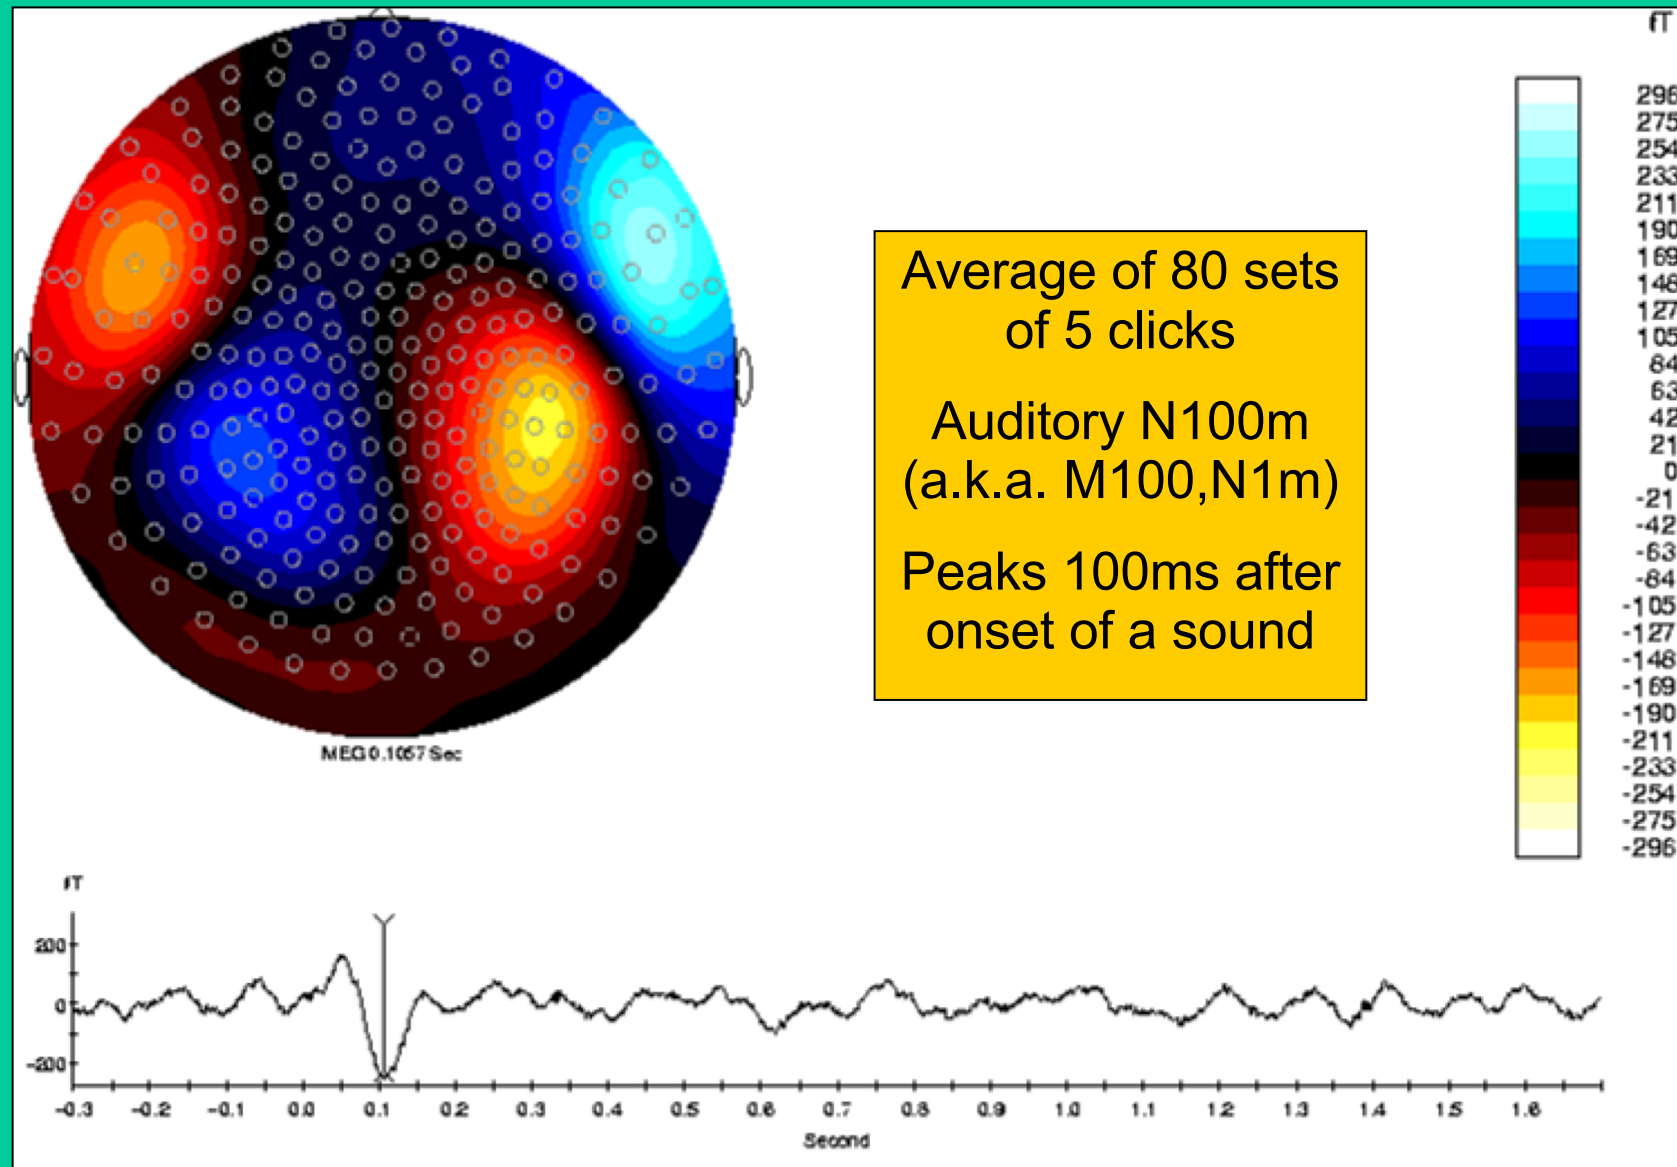

What are we looking for?

- Individual spikes or complex waveforms  
e.g. epileptic spike, sensory evoked response
- Oscillations at particular frequency bands  
e.g. theta (4-8Hz), alpha (8-13Hz), beta (14-30Hz),  
gamma (30-50Hz)

- Evoked Fields

- Time series averaged around an event
- Often early sensory or motor responses

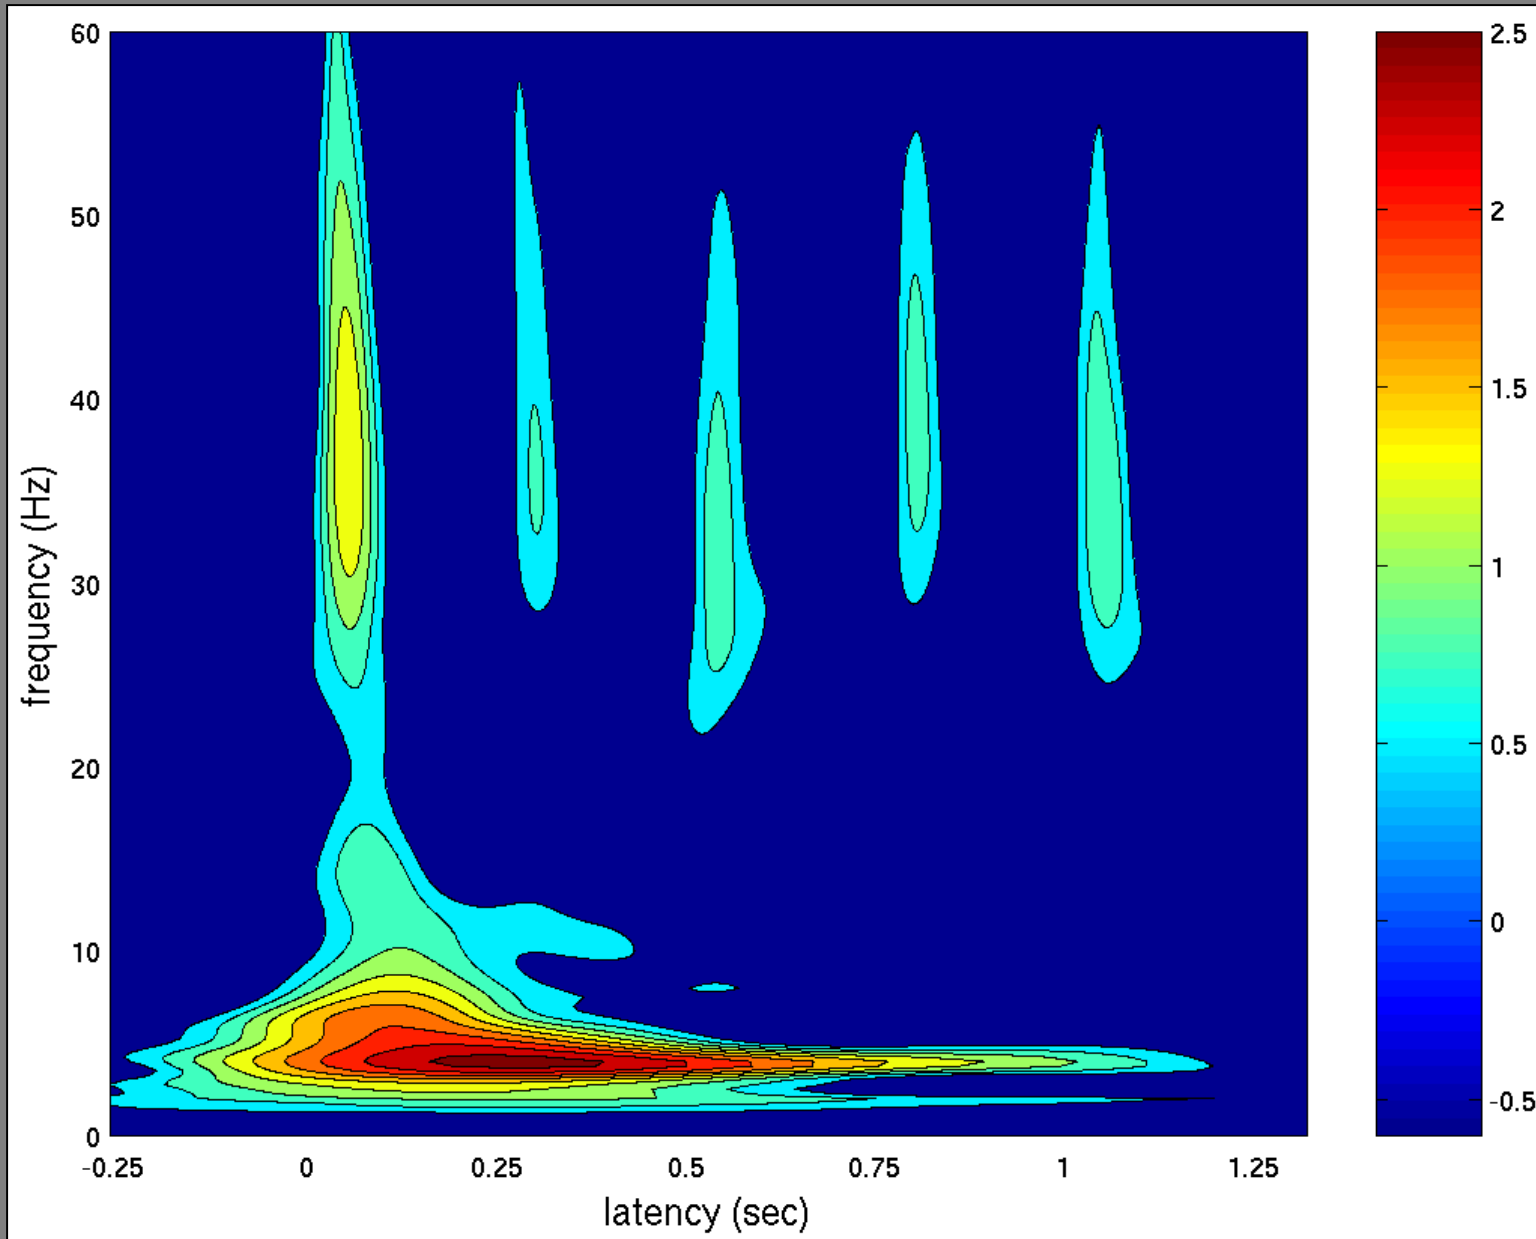

# Event-related Fields (ERFs)

- More complex / later / depend on experimental context
- Can be 'induced' meaning not phase locked to stimulus

# Time-frequency Analysis

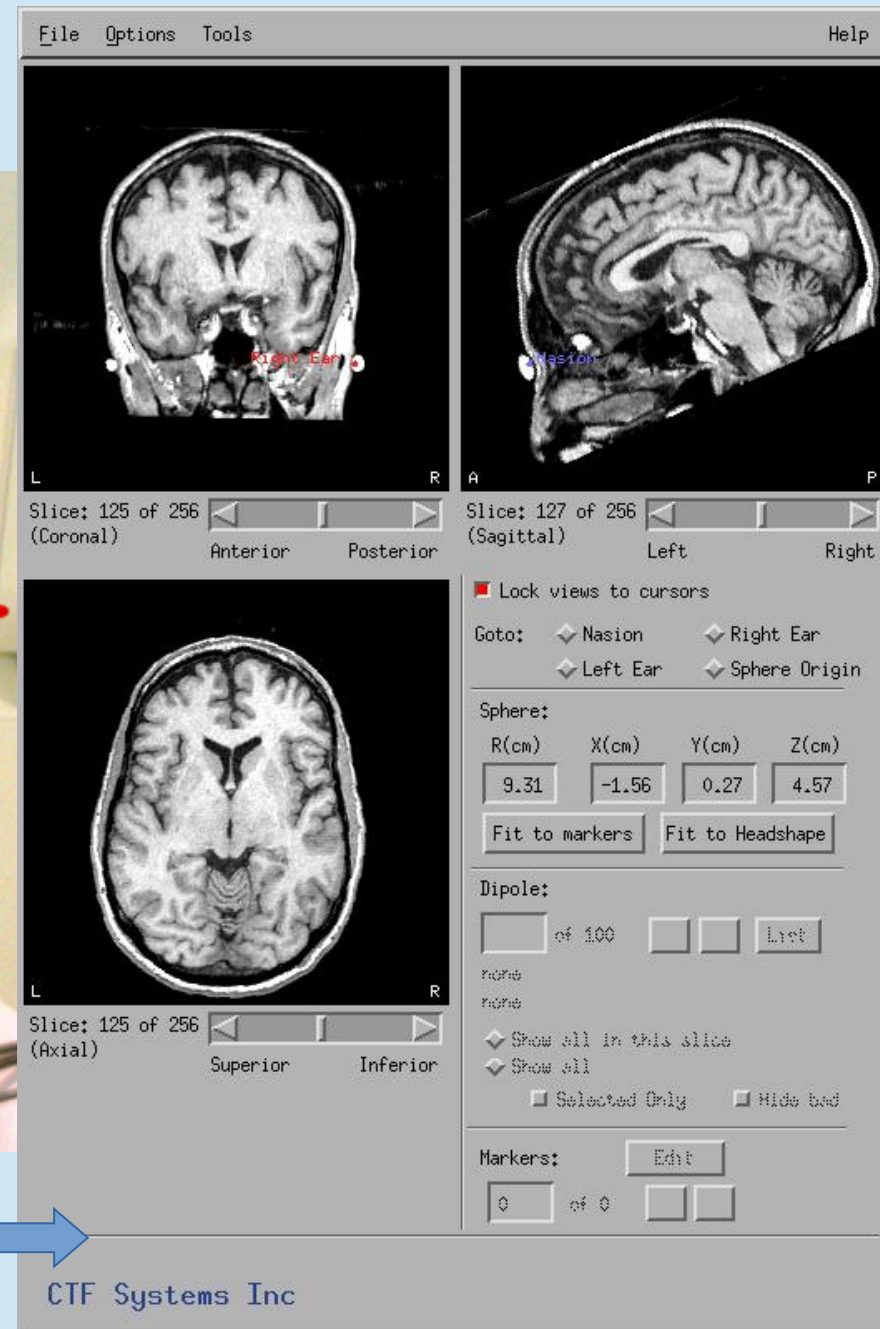

Evoked Response to series of five clicks separated by 250ms

# How do we estimate the source of the MEG signals?

The coil locations are then marked on an MRI for co-registration

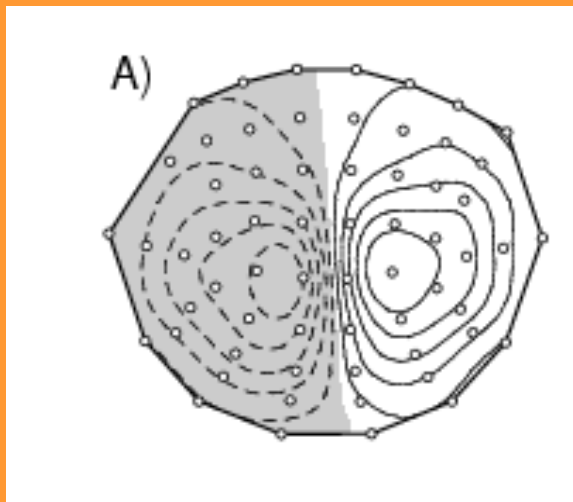

# Dipole Fit

Find the one or more sources that best fit data at single time point

# SAM (Synthetic Aperture Magnetometry)

- Produces whole brain estimates of source power for specified time window and frequency band
- Creates a spatial filter (beamformer) for each voxel to block out activity from other locations
  - Not good for correlated sources
  - Can generate 'virtual channels' at each voxel
- Subject group analysis can be conducted with AFNI or other fMRI software

Projection of Source  
onto Sensors

Spatial Filter

# Example of SAM Analysis for an N-back working memory task with resting data used as a baseline

# Power Spectra used to determine frequency bands for SAM Analysis

Red =  $2 > 0$   
'synchronization' ?

Blue =  $2 < 0$   
'desynchronization' ?

2-back >  
0-back

Alpha

2-back >  
0-back

Beta

High Gamma =  
Spiking?

2-back >  
0-back

High Gamma

# MEG and fMRI

2-back vs 0-back, same 12 subjects

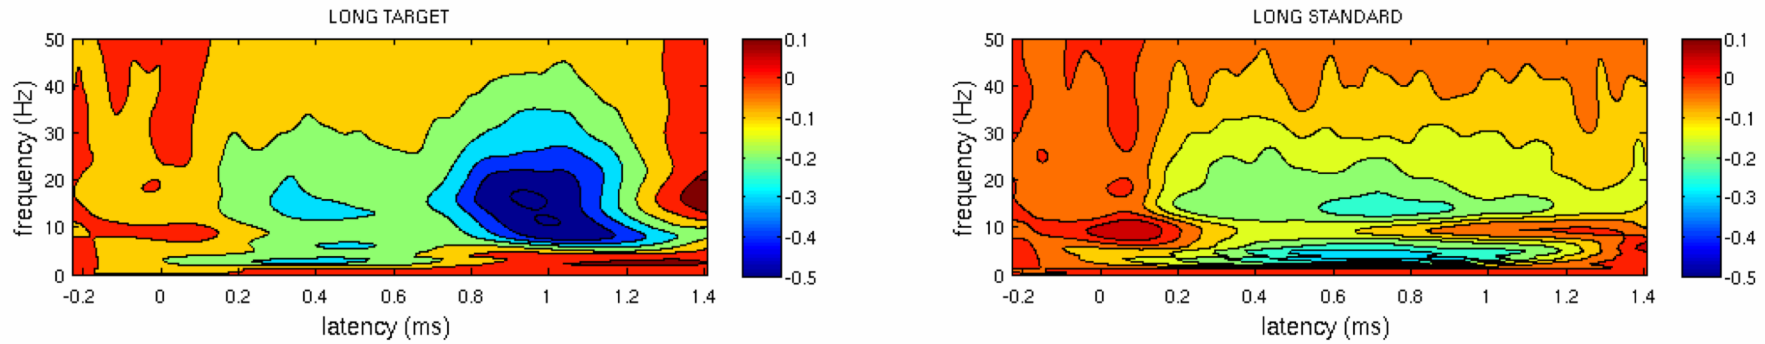

SAM, 500 msec window centered on response, Beta desynchronization

SPM T map 2b>0b {SPM99 t ~ 4.0;  
 $Z_{\equiv} \sim 3.10$ , p ~ 0.001, k > 10}

# Localization not as precise as fMRI, but enhanced temporal resolution. Example from a tone duration experiment

Long non-target tone, < 2s in a loop

Carver et al., 2012

# Deep Sources

Long deemed to be impossible to observe, but really just a matter of signal-to-noise. Modern MEG systems make it possible.

Cerebellum

Amygdala

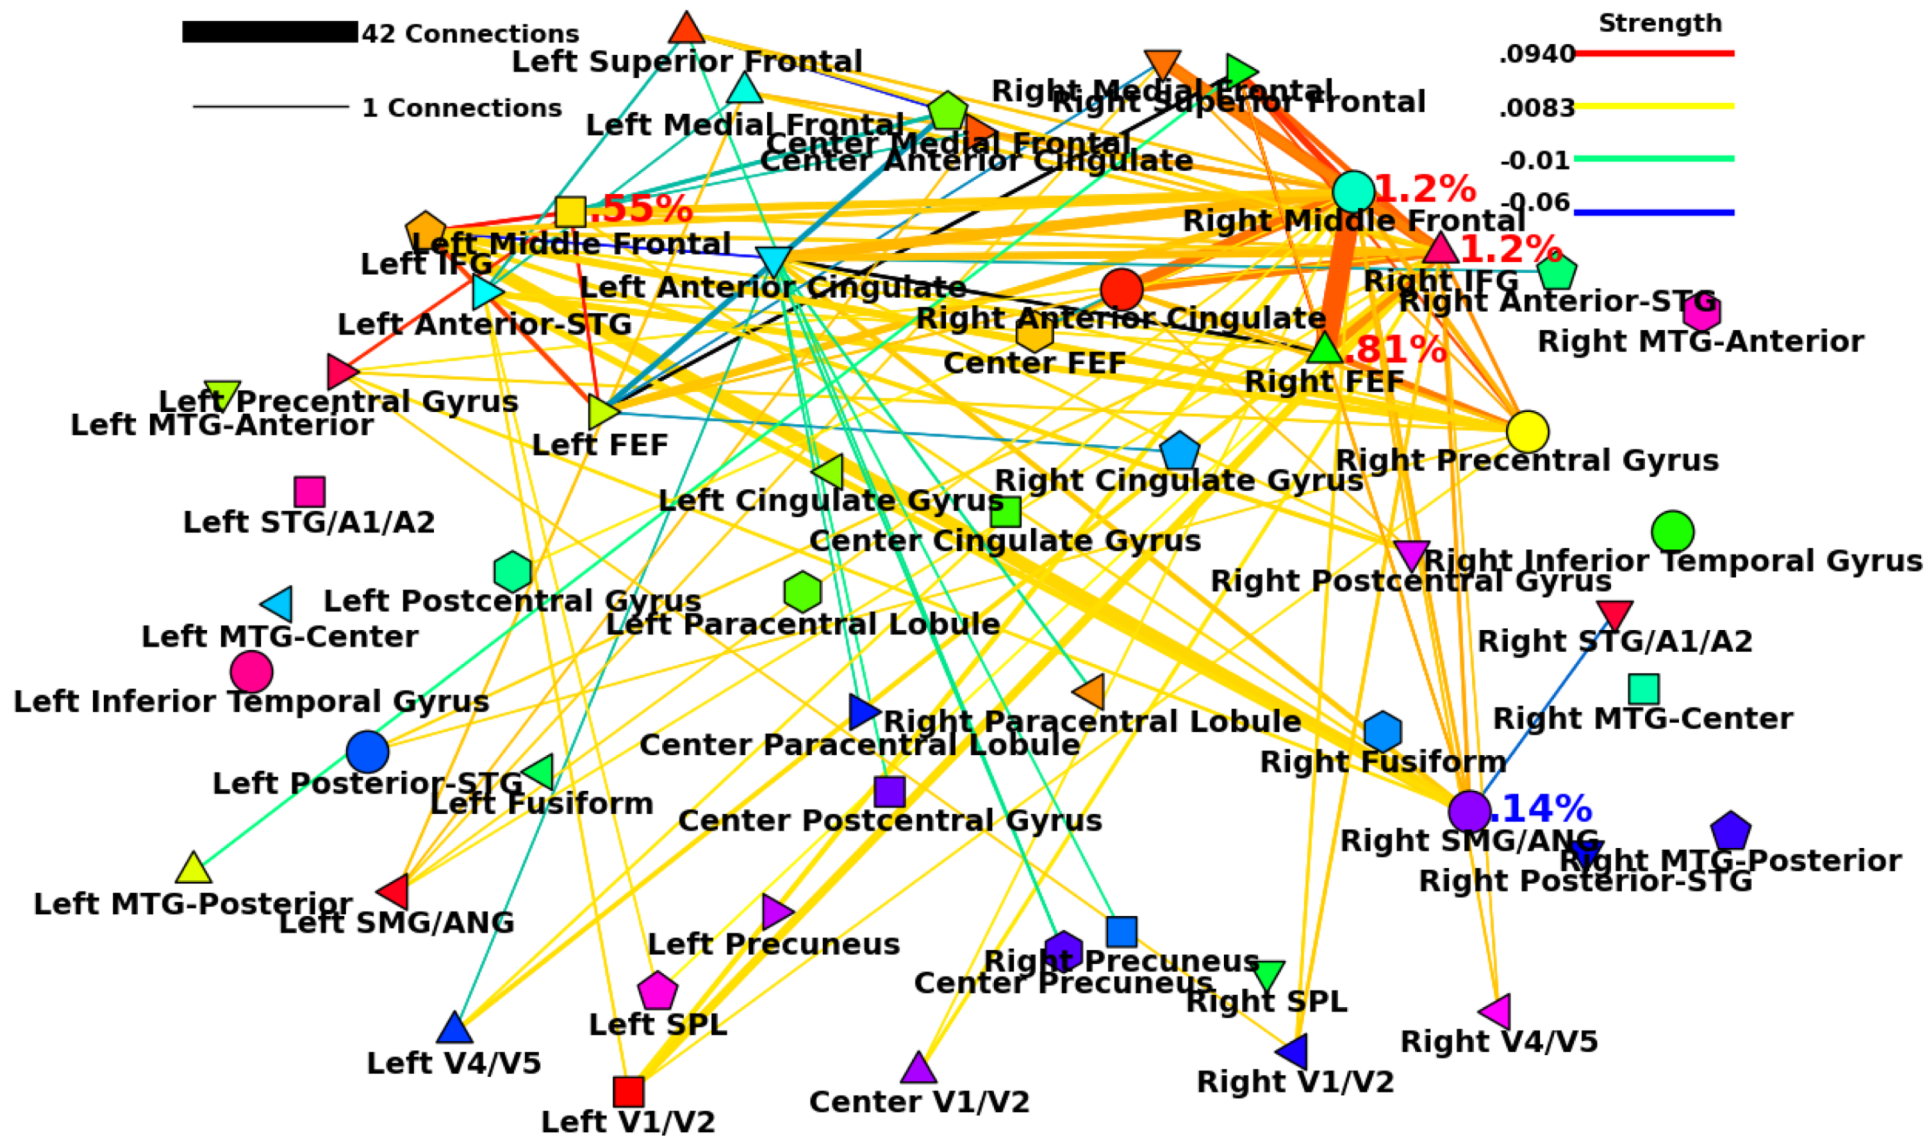

Hippocampus

# Connectivity?

- as yet no predominant method or theoretical underpinning

Power envelope correlation on virtual channels, N-back  
 – Tyler Ard dissertation

Coherence, same data

# Terminology

Magnetometer /  
Gradiometer  
(axial/radial/planar)

Channel

Time series

Topograph
